^aThe estimated millimolar concentrations can be converted into millimoles/10¹⁵ cells by multiplying the concentration by a factor of 28 (L/10¹⁵ parasites). Concentrations (mM) were averaged from n replicates and are shown as mean ± SD.

^bnd, not detected; nq, not quantified.

^cThe compound was not detected in all of the samples from which the average was derived.

^dThe identification of these compounds was largely reliant on a limited number of spectral correlations or signals and should be regarded as tentative.

^eConcentration determined by comparing the integral of the NMR signal with that of the reference compound, TSP, as described in Experimental.

^fEthanol is a contaminant from the ethanol/dry ice bath used during the processing of the parasites prior to extraction.
