1. Introduction

ERM have been commissioned to carry out a Regional Environmental Assessment for the marine aggregates industry (MAREA) in the Humber and Outer Wash Region by the Humber Aggregate Dredging Association (HADA). PMSL were subcontracted to undertake the benthic survey. Within the Humber and Greater Wash region there is a significant amount of available data including benthic grab and geophysical survey data which have been collected for aggregate dredging and offshore wind farm EIAs, aggregate dredging monitoring programmes and for the Humber Regional Environmental Characterisation (REC) survey. The current survey aims to supplement existing data and provide additional spatial coverage in the areas that have the potential to be impacted by dredging activities. The main aim of this survey work is to provide further characterisation of the area in order to produce the MAREA and to inform future site-specific aggregate dredging EIAs.

The survey will entail sampling at 76 stations with single replicates for faunal identification (and a sub-sample for PSA) taken at each site. The sites have been chosen across the licence and application areas and their Maximum Zone of Influence (MZI) and will cover all the EUNIS habitat types within the study area and includes a number of sites in circalittoral coarse sediment which will resample areas surveyed previously to allow an assessment of temporal variability. The data collected at stations will then be combined with data from previous surveys to assess regional scale trends for the MAREA and to build a more detailed knowledgebase for future aggregate dredging EIAs and will also be used to provide additional ground truth data for the REC geophysical survey.

In addition to undertaking benthic sampling the survey also employed a stills camera equipped with a surface umbilical and monitor to view and take images at each sample site prior to a grab sample being taken to prevent disturbance to sensitive Annex 1 species e.g. *Sabellaria spinulosa* formations and identify potential areas of cobble reef or subsea hazards such as wrecks, cables or pipelines. A number of the proposed MAREA survey stations were positioned within the known extent of the biotope SS.SBR.PoR.SspiMx (*Sabellaria spinulosa* on stable circalittoral mixed sediment) which could support Annex 1 reefs of *Sabellaria spinulosa*. These stations have been positioned to provide greater confidence in the extent of this biotope in MZIs where there are fewer existing survey stations.

2. Methods

2.1 Subtidal Survey

Methodologies for grab sampling followed those outlined in the tender specification and also existing best practice guidelines such as the Cefas Guidelines for the conduct of benthic studies at aggregate dredging sites (Boyd, 2002) and other relevant monitoring guidelines e.g. Marine Monitoring handbook procedural guideline 3-9 and other best practice guidelines (Davies et al 2001, DEFRA 2004a, Rees et al 1994, Proudfoot et al 2003, Cooper & Rees 2002, ICES/OSPAR 2000 & DEFRA 2004b).

Surveys were carried out using MV Budding Rose a coded vessel contracted by PMSL. The survey utilised a 0.1m² Hamon grab suitable for sampling coarser marine sediments with an inspection of seabed habitats undertaken prior to sampling using an underwater still camera. The stills camera was used to document the presence of any Annex 1 habitats at the sample sites and also to characterise the benthic habitats in areas of harder ground where grab sampling was not feasible in addition to highlighting any underwater hazards. An assessment of live video footage & stills was made in-situ prior to the deployment of the grab to assess the potential for Annex I habitats (e.g. *Sabellaria* reef or stony/cobble reef). These assessments were made using the currently available guidance notes i.e. Gubbay (2007) for potential *Sabellaria* reefs, and Irving (2009) for potential cobble reefs. This aspect of the project was overseen by Dr. James Allen at PMSL who has carried out a wide variety of video surveys for such reefs for offshore wind farm sites and other commercial developments. In total 76 sampling stations were surveyed based on positions supplied by ERM. The positions utilised in the field depended on the nature of the substrata in that area and took into account small shifts in position to give adequate clearance to sub-sea pipelines or other obstructions e.g. static gear although in general survey positions were within 50m of the original site.

Upon arrival at each site a Kongsberg OE14-208 digital stills camera with lights and flash strobe mounted on a steel frame was lowered over the side. The unit was linked to the surface via an umbilical and controlled via a surface control unit and monitor to trigger the camera and assess seabed habitats in real time. The PMSL digital stills system incorporated a scale bar with 64mm increments (cobble size). At each station the survey area was checked for obstructions and the GPS position for the start and end of the video drop logged by GPS with other notes taken as appropriate regarding the nature of the seabed. The camera was lowered to the seabed and the vessel allowed to drift over the survey site periodically dropping to the bed to take stills. Stills were downloaded at the end of each day and archived to hard drive and DVD.

Following an assessment of the site by drop down stills camera the Hamon grab was deployed at the planned survey location and the resulting sample recovered. Upon retrieval the sample was deposited into a container and sample volume assessed. Samples with a volume of less than 5 litres were stored and a repeat sample taken with a minimum of three attempts used to collect a suitable sample. If samples were consistently substantially less than 5 litres at a given site then expert judgement was used to assess the adequate minimum representative sample size and evaluate repositioning of the site or abandoning

the site altogether. Following a successful grab photographs of the sample were taken and notes regarding sediment type were made.

Prior to sieving the grab samples were sub-sampled for sediment particle size analysis (PSA). Approximately 500 ml of sample was taken using a plastic scoop and the sediment sub-samples were labelled and refrigerated or transported in a cool box prior to PSA undertaken in the laboratory. The PSA sample analysis also included an assessment of the percentage of the sample that was composed of cobbles. In cobble habitats a larger PSA was taken as required.

A full survey log was maintained throughout the survey detailing time of sampling, GPS position, number of attempts required, station number, water depth, physical characteristics of the sample and presence of any other relevant features. If required, stations were repositioned slightly to obtain adequate and representative samples (e.g. if the original site was located on hard ground or if underwater hazards were in the immediate vicinity) but usually this was within 50m of the original position.

Sample processing was then undertaken on a sequential basis utilising a nested sieving technique to reduce the potential for small and delicate invertebrates being damaged by cobble and gravel. Each acceptable sample was removed from the sample container and placed into a hopper and sieved onboard through a larger sieve (e.g. 5 or 10mm) and then through a 1mm sieve (1mm sieve) in order to separate large sediment types and reduce damage to invertebrates. The sieved residue was then gently back-washed into sealable containers and borax buffered 4% formo-saline solution was added as a fixative. Each sample was labelled clearly on the lid and an additional waterproof label placed in the container.

2.2 Laboratory Methodology

All laboratory methodologies are based on best practice and follow tried and tested method statements widely acknowledged within the industry (Worsfield et al 2010, Rees et al 1990, Barnett 1993, Turner 1999, Cooper & Rees 2002, Boyd et al 2002, Prior et al 2004 & Proudfoot et al 2003). Precision Marine Survey Limited are members of the National Marine Biological and Analytical Quality Control scheme (NMBAQC), and their principal taxonomist was until recently a member of the NMBAQC steering committee.

Two experienced members from PMSL undertook the sample sorting, conducting all the sieving, sorting work and sample description. A third member of staff carried out standard sorting quality control. Similarly, experienced taxonomists carried out the identification of the sorted fauna, with an additional member of staff carrying out standard identification quality control. A standard sample tracking procedure was followed throughout the analysis period. All members of the taxonomic analysis and data manipulation staff have at least 18 years marine biological experience with a significant and extensive range of experience in the field of benthic sample analysis and interpretation.

Sorting

The sorting methodology was as follows;

Each sample was washed through a nest of sieves, with a smallest mesh aperture of 1mm, to remove the preservative and partition the sample for ease of sorting. The residue from each sieve was then gently washed into separate white trays. Water was added to the trays and the contents agitated. Immediately after agitation, the light fraction was decanted to another tray. This procedure may be repeated up to 3 times, and each tray of light fractions examined separately to the heavy fraction.

The trays were marked with the appropriate sample code (relating to the client, date, specific site, sample and replicate number). All fractions were then examined as a monolayer under water in white trays, both by eye under a fluorescent bench light and 1.5x illuminated magnifier to remove larger animals with the remaining residue from the light and heavy fractions decanted into petri dishes for further sorting by binocular stereo microscope (6x to 10x magnification). The fauna and residue derived from this process was then retained and stored by group in appropriately labelled containers and each fraction was then decanted into separate 100mm petri dishes and examined under a stereoscopic microscope with 20x eyepieces giving a maximum magnification of up to 80X. The fauna derived was added to the retained containers, preserved and stored ready for identification.

Taxonomic Identification

The procedure for the identification of the sample material was as follows:

Identification was carried out using Olympus SZ40 zoom microscopes with 10X and 20X eyepieces, giving a maximum magnification of up to 80X. An additional 2X objective was also used to increase the potential magnification to 160X where needed. Olympus BX41 compound microscopes were used for further magnification, up to 800X.

Identification of infaunal samples was to the lowest possible taxonomic level (i.e. species) and during identification all individuals were initially separated into families, with part animals being assigned to families where possible. The macrofaunal animals were identified to species level using standard taxonomic keys, low and high power stereoscopic microscopes and dissection, when necessary, for identification. Incomplete animals without anterior ends were not recorded as individuals to be included in the quantitative dataset. However, they were identified where possible and recorded as present. Similarly, motile and colonial or encrusting epibenthic taxa were only recorded as present and not included within the infaunal quantitative data set.

The taxonomic literature used was essentially as given in Rees et al (1990) and other more recent taxonomic publications or workshop (NMBAQC) proceedings and reporting nomenclature used the World Register of Marine Species (WoRMS) database (Appeltans, 2011) or Howson, C.M. & Picton, B.E., 1997 as required.

Biomass

Biomass analysis was performed by wet weight (tissue blotted) and carried out for the five major taxa types (polychaeta, crustacea, mollusca, echinodermata and others) in each sample. Each group was placed on blotting paper for 30 seconds, to allow absorption of preservative into the blotting paper, following this time period the individuals were placed

on a microbalance and the reading taken. The macrofaunal organisms were then placed back in their respective pots and stored. Biomass calculations included all identifiable fragments and calculated to $\pm 0.1\text{mg}$ and all biomass data were recorded in grams or fractions thereof. An estimation of dry weight biomass was made using available published conversion factors for the predominant taxonomic groups from Rumohr et al (1987).

Sediment Analysis

Sediment samples were processed for PSA as per NMBAQC guidelines. Particle size analysis was carried out using a combination of dry sieving and laser granulometry methods. Each sediment sample was first mixed thoroughly until homogeneity is reached. A sub-sample was then passed through a 1mm mesh sieve to remove the >1mm fraction which was then discarded. The <1mm fraction of the sub-sample was analysed by laser granulometry using a Malvern Mastersizer 2000. The Malvern Mastersizer 2000 laser analysette is built to ISO 13320-1 specifications and measures diameters ranging from 0.02 to 2000mm using laser diffraction. The Mastersizer is calibrated annually to conform to Malvern's QSpec Validation criteria. It is cleaned and aligned before taking all measurements. The rest of the homogenised sample was then dried for 48 hours at 84°C to remove all moisture and weighed. The sample was then rehydrated and passed through a 1mm sieve by wet sieving. The <1mm fraction was then retained and allowed to settle, the >1mm fraction was dried for 48 hours at 84°C and passed 'dry' through a nest of sieves, comprising of a 1mm, 1.4mm, 2mm, 2.8mm, 4mm, 5.6mm, 8mm, 11.2mm, 16mm, 22.4mm, 31.5mm 45mm and 64mm and up to 90.5mm i.e. 0.5 phi fractions from 0 to -6.5 phi. Each sample was sieved for a period of 20 minutes and material retained on each sieve fraction weighed. The weight of the <1mm fraction was obtained by the addition of the weights from all sieve fractions and subtracting the value from the original dry weight of the sample.

Data from the >1mm dry sieve method was scaled so that >1mm class weights total 100%. Data from the <1mm laser granulometry method was scaled so that <1mm class weights total 100%. Sieve and laser proportions are then calculated using weights obtained from the dry sieve process to obtain a merged data set.

The statistics derived from the data include mean grain size, skewness, sorting coefficient and bulk sediment classes (% silt, sand & gravel). These were calculated using GRADISTAT v7, a grain size distribution and statistics package developed by Dr. Simon J. Blott of Kenneth Pye Associates Ltd. The methods are consistent with the (best practice) procedures identified by the National Marine Biological Analytical Quality Control scheme.

3. Survey Summary

The benthic survey mobilised on Monday 11th April 2011 and the survey was completed on Saturday 16th April 2011. Weather ranged from 15-20mph S to SW with slight to moderate sea conditions on the 12th April with winds then reducing to 10-15 mph SW (slight sea state) on the 13th April and 5-10 mph SSW (slight sea state) thereafter. Representative samples were taken at all sites although at five sites - REA8, REA22, REA28, REA56 and REA76 low sample volumes were collected (approx. 2l) due to seabed conditions (e.g. consolidated coarse sediments or harder material such as harder cobble or clay under surficial

sediments). These samples however were representative of the surficial sediments in the area and the samples have been processed and included in the final dataset as this does not appear to have overly influenced species diversity. At 1 site (REA30) the sediments from grab samples were variable as identified during video and two separate samples were taken. The majority of sites exhibited coarse mixed sediments with combinations of sand, gravel and shell or pebbles with occasional cobble. Cobbles were identified during the video assessment and occurred in varying quantities at many sites but were often patchy with much of the coarser fraction in the pebble size range and cobbles were rarely picked up in any quantity in the grabs. PSA data indicates that many sites had a significant coarse fraction at just under the cobble grade (64mm). No evidence of Annex 1 habitats such as *Sabellaria* or cobble reef were recorded during video and whilst some low level encrustation or small clumps of tubes were occasionally noted (e.g. sites 23 and 35) they were not in sufficient quantity, area or elevation to qualify as reef although they are likely to qualify as *Sabellaria spinulosa* biotopes. Sites with higher cobble content recorded during video (e.g. site 1) tended to have limited elevations and coverage by reef fauna/flora with moderate or patchy coverage by cobble and were also not considered to be reef.

In many areas epibiota recorded during video was relatively sparse (particularly in cleaner sand or gravels) with occasional crab (*Liocarcinus* sp.), echinoderms such as *Asterias rubens* or *Crossaster papposus* and anemones (e.g. *Urticina* spp.) most obvious along with encrusting fauna such as barnacles and polychaetes (*Pomatoceros* spp.) on stones. More mixed sediments with a wider variety of sediment types and larger stones, pebbles or cobble tended to have richer epibiota with a hydroid/bryozoans turf (e.g. *Haleciun* sp., *Hydrallmania* spp., *Nemertesia* sp. *Alcyonium* sp. *Flustra foliacea*, *Vesicularia spinosa*, *Electra* spp. and encrusting calcareous red algae). Such areas often also included examples of ascidians such as *Dendrodoa grossularia* and a variety of anemones, ascidians such as *Dendrodoa grossularia*, occasional sponges and other echinoderms such as *Echinus esculentus*. However, in most areas epibiota was still relatively patchy and coverage by hydroid/bryozoan turf and other encrusting/colonial taxa was often relatively sparse. A summary of species recorded from the drop down stills camera is provided in Table 2 and a series of representative of stills for each site from the drop down camera survey is provided in Appendix 1. .

The site positions for the survey along with notes on dates/time, water depth, sampling effort and sediment type in each grab are given in Table 1 and a map showing the distribution of sites is provided in Figure 1. The information from the stills in conjunction with some preliminary analysis of infaunal data (Appendix 2) was then used to derive Eunis (biotope) codes to Levels 4 and 5 (where possible). It was evident from analysis that many habitats fall under the coarse or mixed sediment section of the classification and these habitats are currently less well defined under the current (2004) biotope classification due to lack of available data. These habitats are currently under review by JNCC and until the revised classification is available many biotopes from the current survey will be provisional, particularly in areas with coarse/mixed sediments and those with transitional communities. Other recent surveys (e.g. the Humber REC) have attempted to identify additional biotopes to address this although the status of these is currently unknown (in relation to the UK classification) and they are primarily of use in interpretation of REC benthic surveys data. There is also some variability in assigning habitats to coarse or mixed sediments in

gravelly/stony habitats whereby the current UK biotope classification includes coarse sands or sandy gravels in the coarse section whilst other studies (e.g. the Humber REC) restrict coarse sediment to those with >80% gravel. Many coarse sediment habitats are also inherently heterogenous with a wide range of coarse fractions along with finer sands and could therefore be classified as mixed sediment. In the current study provisional Level 4 and 5 Eunis codes based on video and infaunal data have been assigned where possible with transitional or uncertain habitat/biotope codes also highlighted (e.g. by providing two codes). To provide some correlation with the Humber REC data the closest matching REC biotope code has also been provided which includes the new biotopes defined by these studies although more detailed analysis would be required to confirm these. The status of such habitats/biotopes will be assessed following updates to the classification by JNCC and by more detailed analysis of the current data set in conjunction with wider historic data sets which will be undertaken as a separate component to this project. Provisional biotopes for each site are provided in Table 3 and some outputs from analysis of infaunal/particle size data used to assist in biotope assignation are also provided in Appendix 2.

Table 1. Survey site positions.

Site	Depth (m)	Depth (m CD)	Attempts	Latitude	Longitude	Date/Time	Sediment

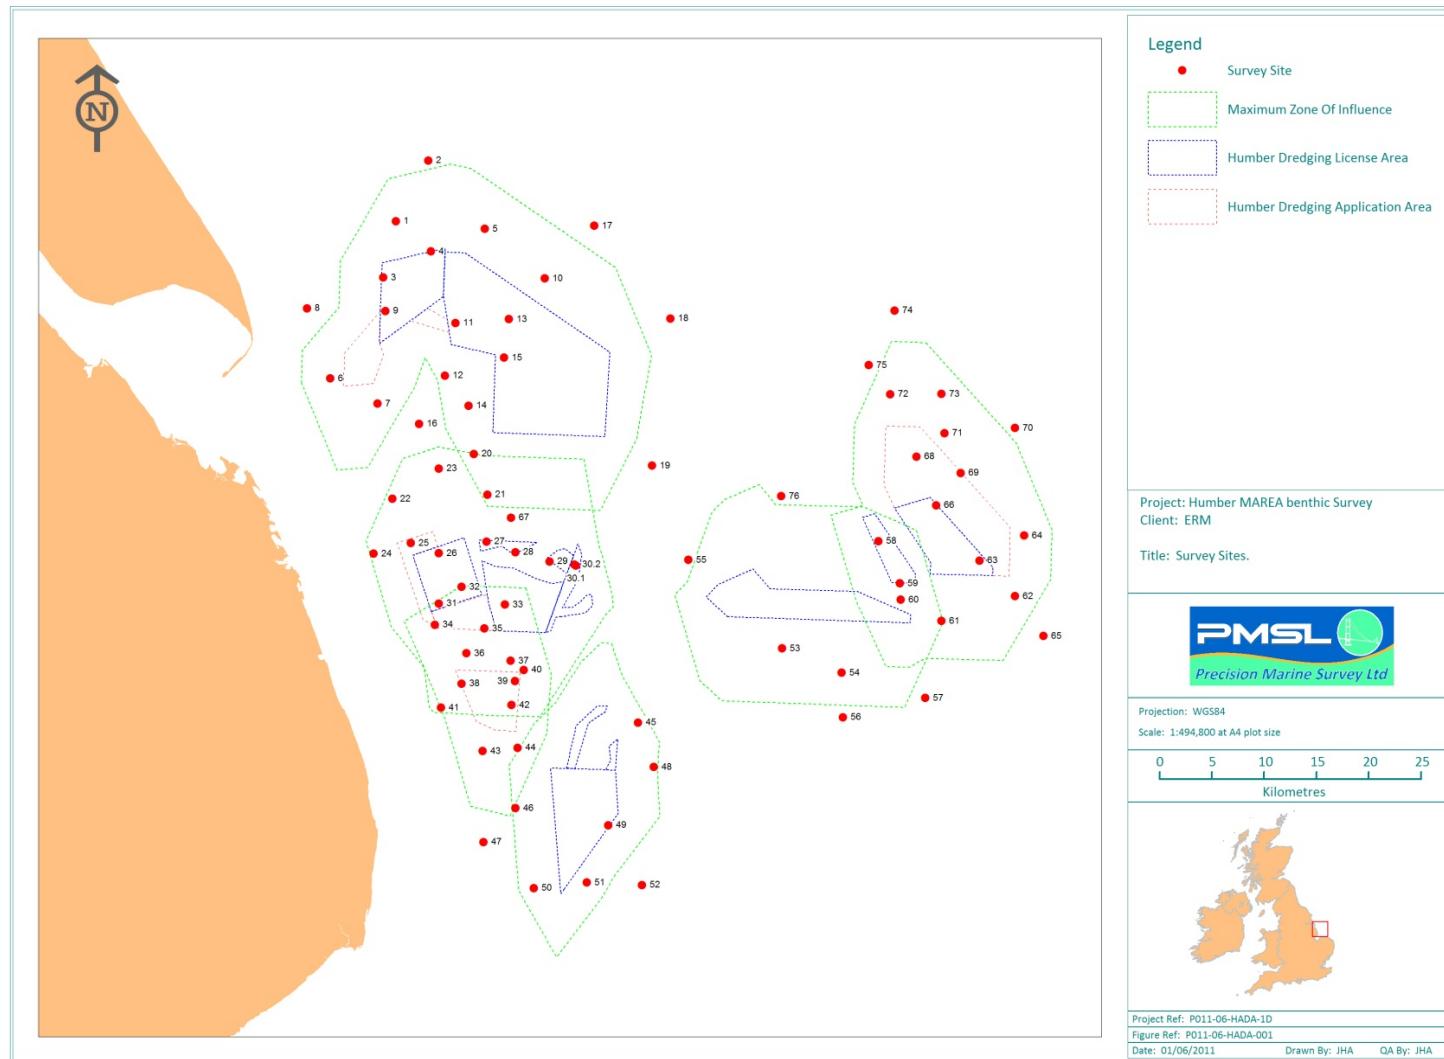

Figure 1. Humber REA sampling sites.

Table 2. Summary of seabed types and species recorded from drop down photography.

Site	Substrate	Species
1	Slightly silty gravel & pebbles with occasional cobble.	Flustra foliacea, hydroids, Pomatoceros sp., barnacles, Echinus esculentus, Asterias rubens, seasquirts and Pholis gunnellus.
2	Gravel & pebbles & shell with occasional cobble.	Alcyonium digitatum, Flustra foliacea, hydroids (incl. Nemertesia sp.), Pomatoceros sp. and Necora puber.
3	Gravel & pebbles with occasional cobbles.	Occasional Flustra foliacea, Ianice conchilega, barnacles, hydroids, seasquirts and Urticina felina.
4	Clean gravel & pebbles.	Sparse, occasional conchilega & hydroids.
5	Slightly silty gravel & pebbles with some cobbles and occasional boulder.	Flustra foliacea, hydroids, Pomatoceros sp., barnacles, Crossaster papposus, Echinus esculentus and Urticina felina.
6	Clean sand.	No visible fauna.
7	Slightly silty pebbles, cobbles and occasional boulder.	Flustra foliacea (Frequent-Common), hydroids, Pomatoceros sp., barnacles, Henricia sp., seasquirts, sponge and encrusting red seaweed.
8	Gravel, pebbles and shell.	Sparse, occasional Lanice conchilega & Urticina felina.
9	Patchy sand, pebbles and some cobbles.	No visible fauna across most of transect, few hydroids and seasquirts toward end of transect.
10	Gravel, shell and pebbles.	Sparse, occasional Flustra foliacea, hydroids and Urticina felina.
11	Gravel, shell and pebbles.	Sparse, occasional Lanice conchilega, Paguridae sp. & Urticina felina.
12	Slightly silty gravel, pebbles and cobbles and occasional boulder.	Flustra foliacea, hydroids, Pomatoceros sp., barnacles, seasquirts, Urticina felina, sponge, Cancer pagurus and encrusting red seaweed.
13	Gravel and pebbles.	Few barnacles and Pomatoceros sp.
14	Slightly silty gravel, pebbles, some cobbles and occasional boulder.	Hydroids, Pomatoceros sp., barnacles, Asterias rubens, Crossaster papposus, Echinus esculentus, Urticina felina, seasquirts, Lanice conchilega and encrusting red seaweed.
15	Patchy sand, pebbles and some cobbles.	Flustra foliacea, hydroids, Pomatoceros sp., barnacles, Urticina felina, seasquirts and encrusting red seaweed.
16	Slightly silty gravel & pebbles with occasional cobble.	Flustra foliacea, hydroids, Pomatoceros sp., barnacles, seasquirts, Calliostoma zizyphinum, Crossaster papposus, Henricia sp., Echinus esculentus, Cancer pagurus and encrusting red seaweed.
17	Clean sand with patchy areas of shell and gravel/pebbles.	Sparse, occasional hydroids/erect bryozoans.
18	Gravel, shell and pebbles.	Patches of Flustra foliacea, hydroids (incl. Nemertesia sp.) and barnacles with Echinus esculentus, Asterias rubens and Urticina felina.
19	Gravel, pebbles, sand and some cobbles.	Bryozoans, hydroids, Pomatoceros sp., barnacles, encrusting red seaweed, Crossaster papposus, Echinus esculentus and Urticina felina.
20	Gravel, pebbles, sand and some cobbles.	Flustra foliacea, hydroids, Pomatoceros sp., barnacles, seasquirts (incl. Didemnidae sp.), Urticina felina, sponge, Asterias rubens, Crossaster papposus, Cancer pagurus and Henricia sp.
21	Slightly silty gravel & pebbles with occasional cobble.	Patches of Flustra foliacea, hydroids, Pomatoceros sp., barnacles, seasquirts, and sponge with Urticina felina, Asterias rubens, Crossaster papposus, Liocarcinus sp.
22	Slightly silty gravel & pebbles with occasional cobble.	Patches of Flustra foliacea, hydroids, Pomatoceros sp., barnacles, seasquirts and sponge with Asterias rubens.
23	Slightly silty gravel & pebbles with some cobbles.	Patches of Flustra foliacea, hydroids, Pomatoceros sp., barnacles, seasquirts, and sponge with Urticina felina Calliostoma zizyphinum and Cancer pagurus.
24	Slightly silty sandy gravel and pebbles.	No fauna visible apart from one dragonet.
25	Slightly silty sandy gravel and pebbles.	No fauna visible apart from one Asterias rubens.
26	Slightly silty sandy gravel and pebbles.	No fauna visible.
27	Slightly silty sandy gravel and pebbles.	Appears sparse, few Pomatoceros sp. and Calliostoma zizyphinum.
28	Slightly silty, sandy gravel & pebbles with occasional cobble.	Patches of Flustra foliacea, hydroids, Pomatoceros sp., barnacles and sponge.
29	Slightly silty sand and pebbles.	Sparse, occasional patch of hydroids (incl. Nemertesia sp.), Crepidula fornicata and Urticina felina.
30	Clean sand some gravel/shell debris	No fauna visible.
31	Clean sand.	Sparse, one Asterias rubens

Site	Substrate	Species
32	Fine sand and pebbles.	No fauna visible.
33	Fine sand, gravel and pebbles.	Sparse, patches of hydroids and few <i>Pomatoceros</i> sp.
34	Clean sand.	Sparse, one <i>Asterias rubens</i>
35	Clean sand.	Sparse, small patch of <i>Flustra foliacea</i> .
36	Slightly silty sandy gravel and pebbles.	Sparse, small patches of hydroids &/ bryozoans.
37	Clean sand.	Sparse, few <i>Asterias rubens</i> , <i>Urticina felina</i> , occasional hydroids (Incl <i>Nemertesia</i> sp.) and <i>Vesicularia spinosa</i> .
38	Sand with a few pebbles.	Sparse, small patches of hydroids &/ bryozoans, <i>Cancer pagurus</i> .
39	Clean sandy gravel.	Sparse, <i>Asterias rubens</i> .
40	Clean sand and pebbles.	Sparse, one brittlestar visible.
41	Clean sand with patchy areas of pebbles.	Appears sparse, small patch of <i>Flustra foliacea</i> and hydroids.
42	Clean sand.	Sparse, one <i>Asterias rubens</i>
43	Clean sand.	No fauna visible.
44	Clean sand with small patch of pebbles.	No fauna visible.
45	Fine sand with some pebbles.	Sparse, small patches of hydroids, <i>Alcyonium diaphanum</i> and <i>Vesicularia spinosa</i> & one brittlestar and <i>Lanice conchilega</i> .
46	Clean sand.	No fauna visible.
47	Slightly silty, sandy pebbles and occasional cobble.	<i>Flustra foliacea</i> , hydroids, <i>Asterias rubens</i> and <i>Urticina felina</i> .
48	Clean sand.	No fauna visible.
49	Clean sand with some gravel.	No fauna visible.
50	Slightly silty sand and gravel.	Sparse, few <i>Lanice conchilega</i> , small patch of <i>Flustra foliacea</i> and hydroids/bryozoans.
51	Fine sand and some shell.	Sparse, few brittlestars, <i>Lanice conchilega</i> , small patch of athecate hydroids (probable <i>Turbellaria</i> sp.).
52	Clean sand.	No fauna visible.
53	Sand, gravel, shell and pebbles.	Sparse, patches of <i>Nemertesia</i> and other hydroids, <i>Vesicularia spinosa</i> , <i>Flustra foliacea</i> , barnacles and one <i>Urticina felina</i> .
54	Sand, gravel, shell and pebbles.	Sparse, small patches of <i>Flustra foliacea</i> and hydroids.
55	Clean sand with small patches of shell.	Very sparse, a small patch of <i>Flustra foliacea</i> .
56	Fine sand, shell and some pebbles.	<i>Flustra foliacea</i> , sponge and hydroids and other bryozoans.
57	Slightly silty gravel and shell with pebbles.	<i>Alcyonium diaphanum</i> , <i>Flustra foliacea</i> , hydroids and <i>Henricia</i> sp.
58	Sandy gravel and shell with pebbles.	<i>Alcyonium diaphanum</i> , <i>Flustra foliacea</i> and hydroids (incl. <i>Nemertesia</i> sp.).
59	Sand, gravel, shell, pebbles and occasional cobble.	<i>Flustra foliacea</i> , <i>Echinus esculentus</i> , <i>Urticina felina</i> , barnacles, <i>Liocarcinus</i> sp., other bryozoans and hydroids.
60	Clean sand with patches of shell and gravel.	Sparse, few barnacles and hydroids.
61	Slightly silty gravel and pebbles.	<i>Flustra foliacea</i> , seasquirts, barnacles, <i>Pomatoceros</i> sp. and hydroids.
62	Clean sand with occasional shells and pebbles.	<i>Vesicularia spinosa</i> and hydroids.
63	Sand with patches of gravel and pebbles.	<i>Alcyonium diaphanum</i> , <i>Flustra foliacea</i> , hydroids, <i>Asterias rubens</i> , <i>Paguridae</i> , brittle stars and <i>Urticina felina</i> .
64	Clean sand.	No fauna visible.
65	Clean fine sand with some small patches of gravel and shell.	No fauna visible.
66	Sandy gravel, pebbles and shell.	<i>Alcyonium diaphanum</i> , barnacles, <i>Flustra foliacea</i> , hydroids (<i>Hydrallmania falcata</i>), <i>Alcyonium digitatum</i> , <i>Asterias rubens</i> and <i>Urticina felina</i> .
67	Slightly silty gravel and pebbles with occasional cobble.	Barnacles, <i>Pomatoceros</i> sp., <i>Flustra foliacea</i> and few seasquirts.
68	Clean sand.	No fauna visible.
69	Clean sand.	No fauna visible.

Site	Substrate	Species
70	Clean sand with patches of coarse sand and bit of gravel.	No fauna visible.
71	Clean coarse sand.	No fauna visible.
72	Clean sand with small patches of gravel.	No fauna visible.
73	Clean sand.	No fauna visible.
74	Sand with small patches of gravel and pebbles.	Alcyonium diaphanum, hydroids (Hydrallmania falcata), Alcyonium digitatum, sponge, seastars, Asterias rubens and Urticina felina.
75	Clean coarse sand.	No fauna visible.
76	Sand, gravel, pebbles, shell and occasional cobble.	Mytilus edulis, Flustra foliacea, barnacles, sponge, Urticina felina and Crossaster papposus.

Appendix 2. Analysis outputs

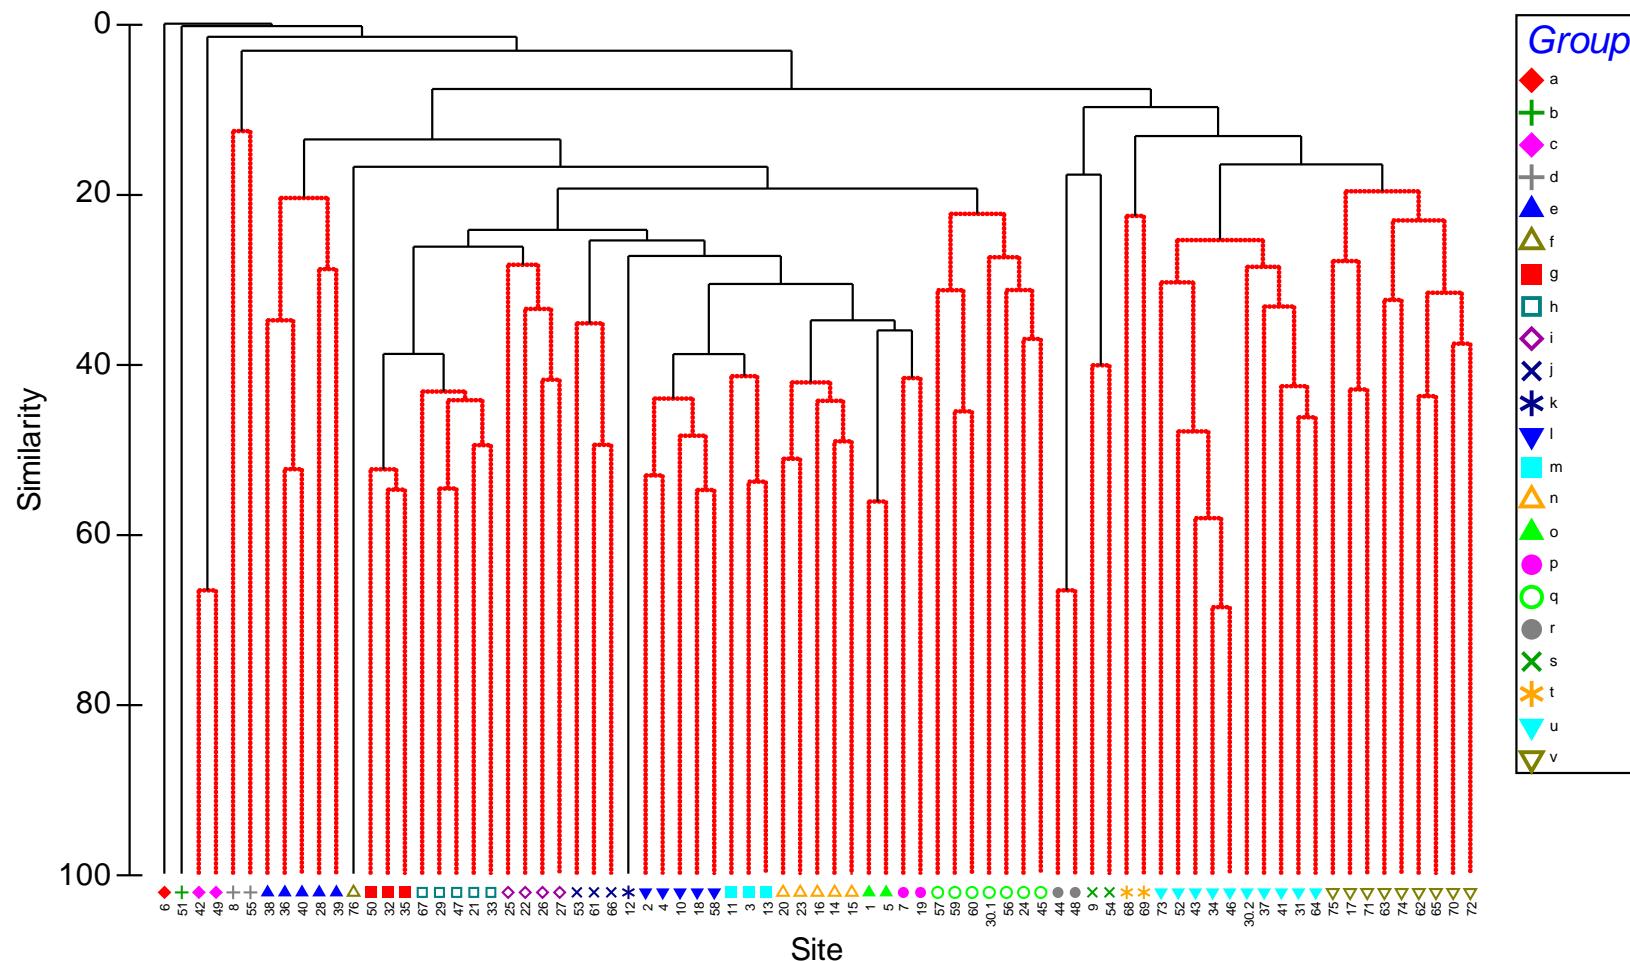

Figure A2.1. Results of cluster analysis on species data.

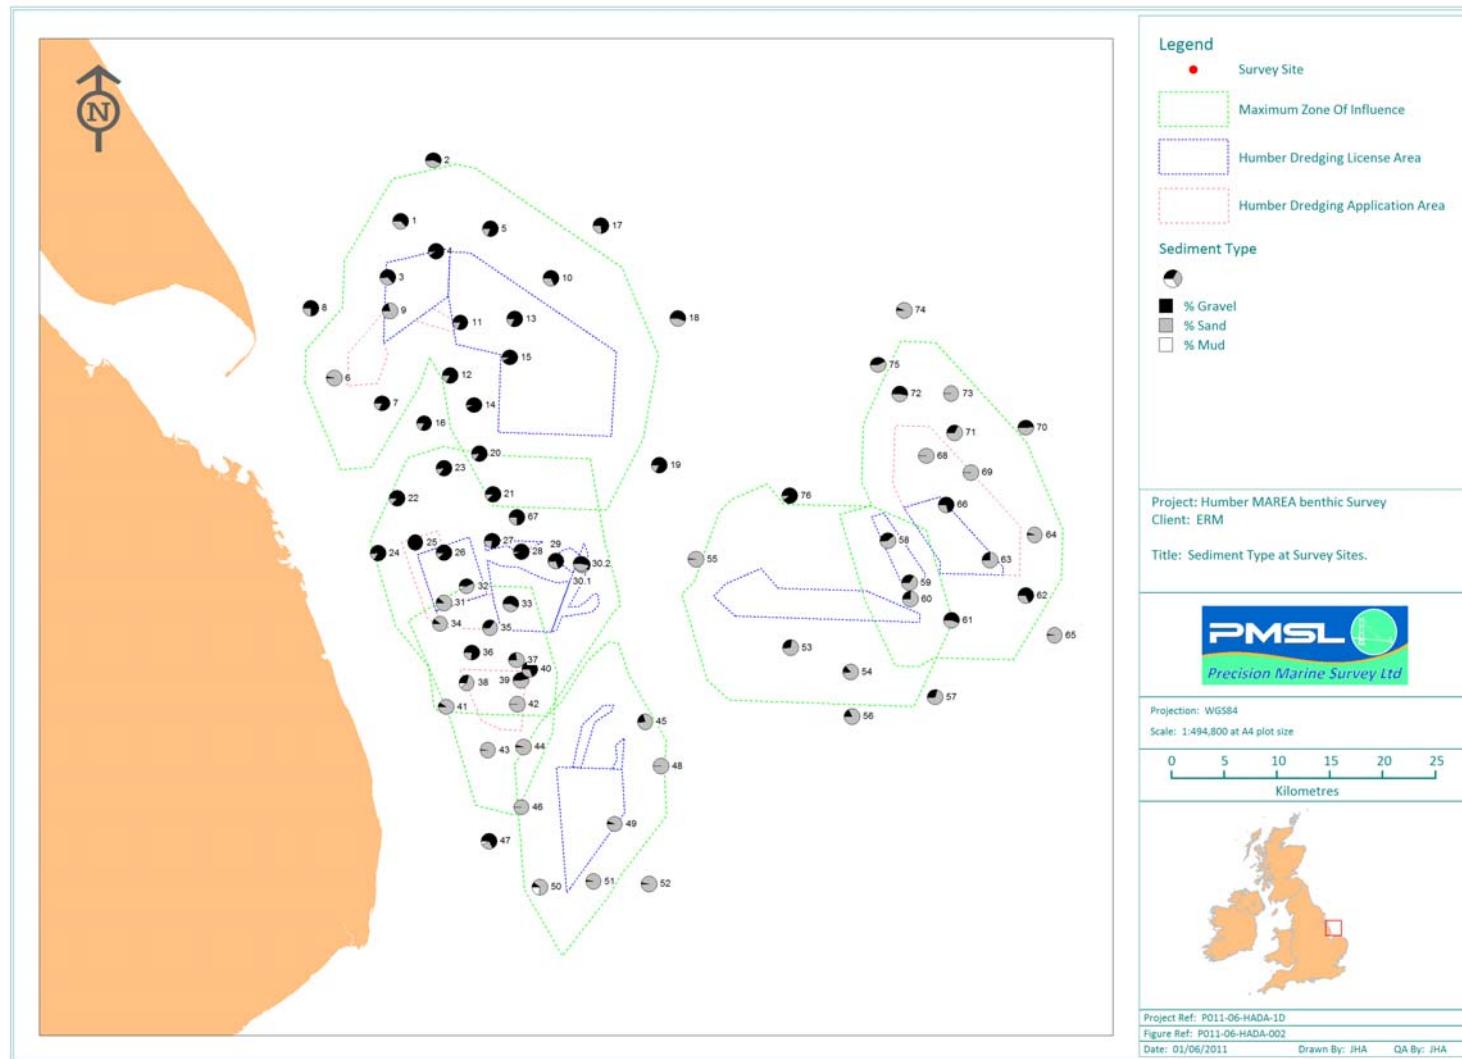

Figure A2.2. Sediment type (bulk sediment class) at survey sites.

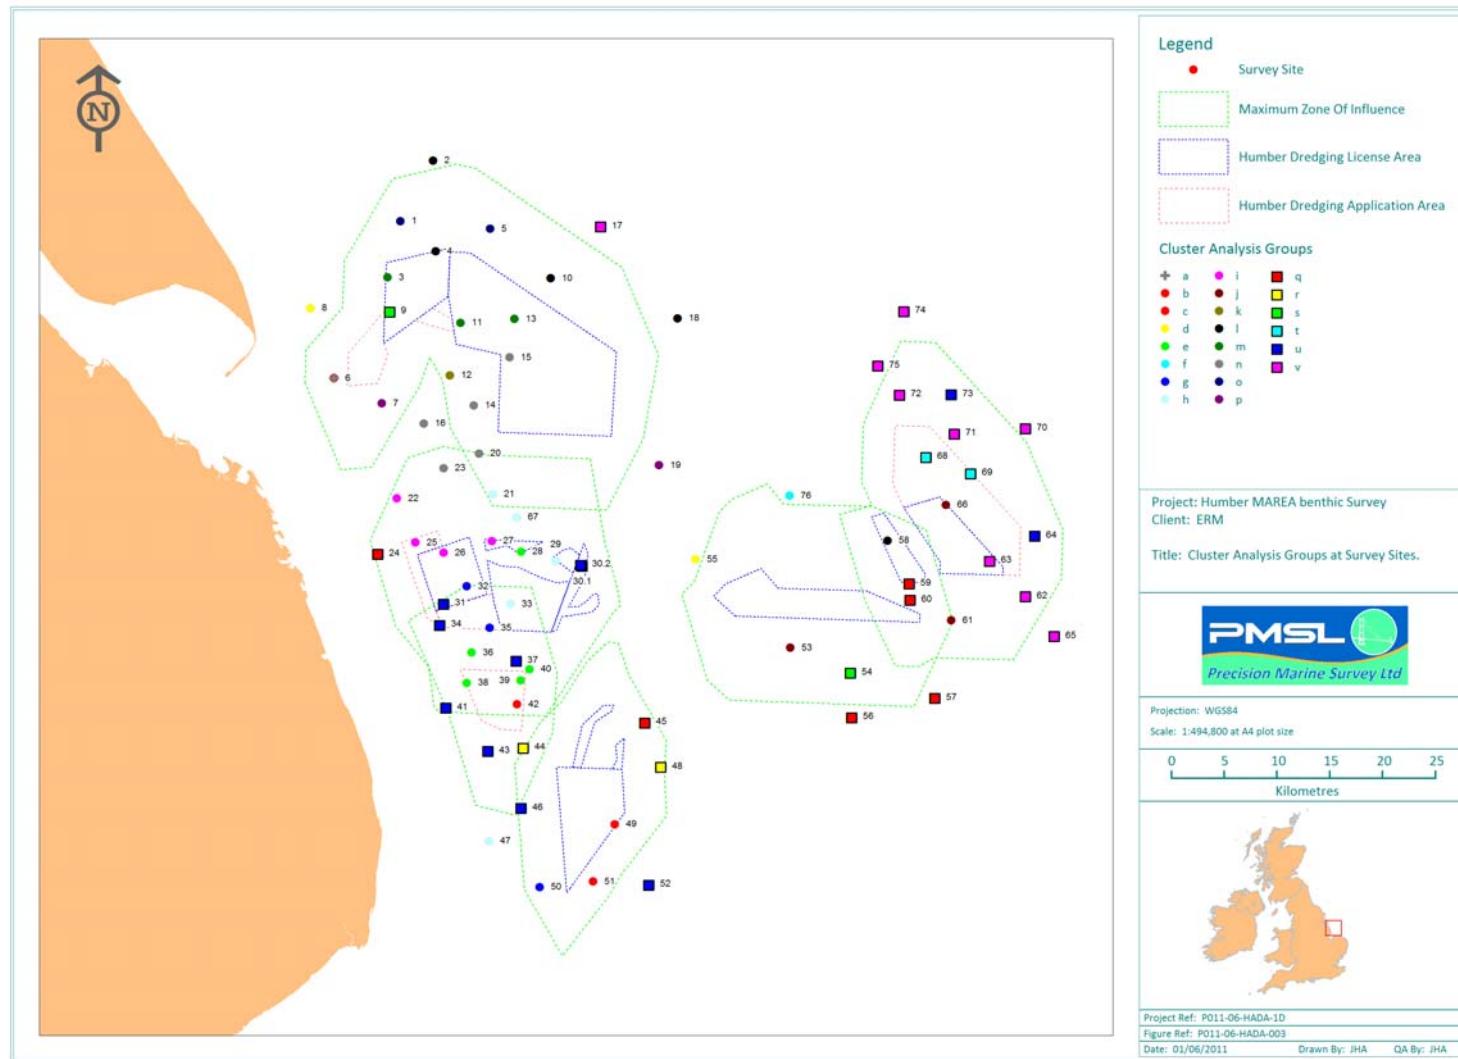

Figure A2.3. Spatial distribution of groups from cluster analysis.

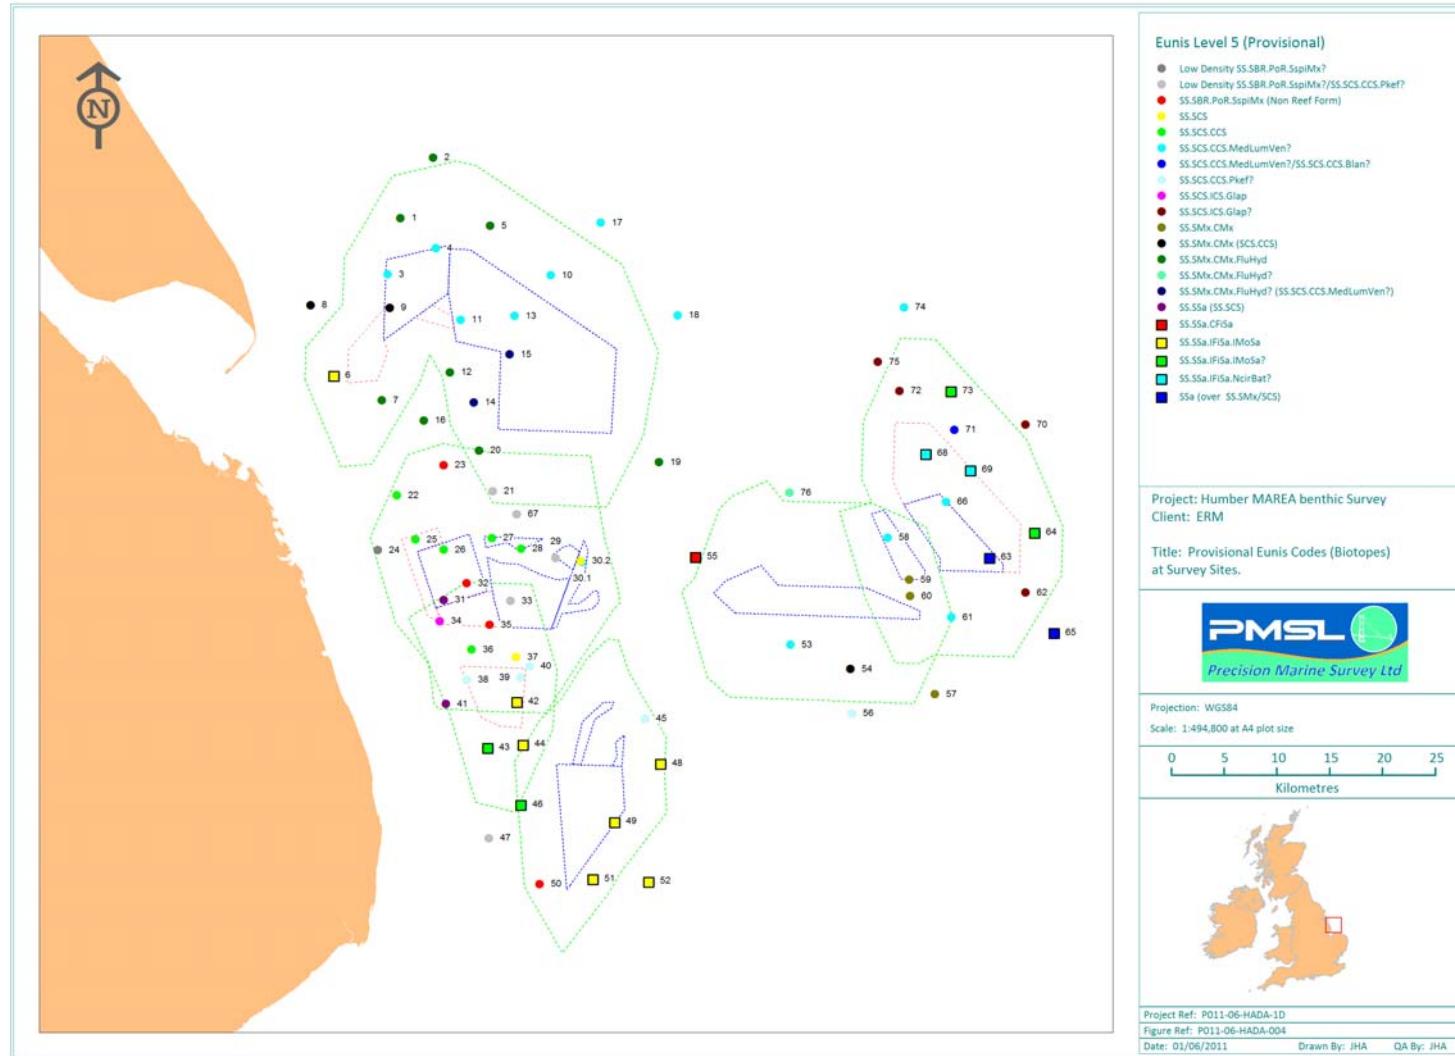

Figure A2.4. Provisional Eunis (biotope) codes.

Table A2.1. Summary of characteristic taxa and sediment type from sites in each cluster group.
